Flowchart

Pseudo Code

```
Set up arcpy environment

# make a feature layer from the parcel feature class for use
# by the SelectLayerByLocation() tool
parcel_layer = arcpy.management.MakeFeatureLayer(...)

# list well paths in the well_data feature dataset
well_path_list = arcpy.ListFeatureClasses(...)

for well_path in well_path_list:   # for each well path, do the following:
    # create an output well buffer name for use by the Buffer() tool
    wellbuf = "Buffers/" + well_path + "_buffer"

    # buffer the current well path by 200 feet
    well_buffer = arcpy.analysis.Buffer(...)

    # select parcels that intersect the well path buffer
    parcels_selected = arcpy.management.SelectLayerByLocation(...)

    parcel_csv = ... # create a file name (full path) for an output csv file
    # call the CopyRows() tool to export a csv file from the selected parcels
    arcpy.management.CopyRows(...)

    mailing_txt = ... # create a file name (full) for an output mailing list
    extract addresses from the parcel_csv file and
    write them into the mailing list file
    (Refer to Lecture 5 Examples 8 & 9 and Lab 4)

    delete the csv file since it is no longer needed

notify the user that the job is done
and where to find the mailing files
```

Flowcharts and pseudo code are tools popularly used in software design and development. Flowcharts are used to layout a general procedure that everybody can read and understand, and pseudo code uses a common language with a programming style to implement the logics of the procedure. This pseudo code is very close to the real code because key tool names and key variables are provided. To complete the project, you need to figure out the input and output of each tool. Refer to Esri online documentaiton for usage and parameters of the tools. Make sure you fully understand Section 2.8) of Lecture 7. Also refer to Lab 6 extract_soil.py about how to pass the output of one tool to another tool as input.
